

Bees are life!

The Maltese honey bee is in danger of being eliminated due to the extreme usage of pesticides on crops.

The extinction of the Maltese bee is very close due to the high usage of pesticides on our crops. Humans depend on bees more than they can imagine. For example, if flowers don't get pollinated, they will die. If that happens, cows won't have anything to eat. Then humans won't have anything to eat.

A huge number of people believe that the only thing bees do is keep buzzing around and getting random people stung. The truth is that honeybees are one of the very main elements in our environment.

Seventy percent of the crop species that provide us with our food are fertilized by bees. Bees tend to be the primary creator of reproduction among living things, as they transfer pollen from male stamens to female pistils.

An extremely large amount of bees have died because of pesticides. This will affect plants, animals, clothing and also humanity. Some plants get pollinated by wind, but that is a very slow process. Although butterflies also pollinate, bees are more efficient.

If bees become extinct, it will also affect animals, but mainly herbivores, who depend on the plants to survive, so they would also be extinct if plants are gone.

The only truth is that by killing bees, we're only hurting ourselves. Our lives depend on the planet's health and its' living things, and we need to face the fact that the planets' life is in danger.
